The contractile responses of the rabbit coronary artery to acetylcholine (Ach) and phenylephrine (PE) were obtained before and after alpha- and beta-adrenoceptor blockade. The smooth muscle responsiveness to the stimulatory and inhibitory effect of Ach were completely or partly abolished by atropine or propranolol, respectively. Adrenaline (0.1-30 mumol/l) caused an increase in the reactivity of pig coronary arteries to Ach, while the responses of human arteries were unchanged. The effect of PE was only partially inhibited by propranolol. Responses to the alpha-adrenoceptor agonist methoxamine (0.1-10 mumol/l) were abolished in pig

One option available to users is information handling systems. An information handling system generally processes, compiles, stores, and/or communicates information or data for business, personal, or other purposes thereby allowing users to take advantage of the value of the information. Because technology and information handling needs and requirements vary between different users or applications, information handling systems may also vary regarding what information is handled, how the information is handled, how much information is processed, stored, or communicated, and how quickly and efficiently the information may be processed, stored, or communicated. The variations in information handling systems allow for information handling systems to be general or configured for a specific user or specific use such as financial transaction processing, airline reservations, enterprise data storage, or global communications. In addition, information handling systems may include a variety of hardware and software components that may be configured to process, store, and communicate information and may include one or more computer systems, data storage systems, and networking systems. Some information handling systems are embedded systems. As embedded systems have become more common in enterprise computing, it has become increasingly important that such embedded systems be secure. One reason for the increased importance of embedded security is that embedded security solutions often must be resilient against attackers who have physical access to the system. Thus, embedded security solutions must be designed to withstand attacks by malicious parties that are located on an attacker's network and have physical access to the system under attack. Many embedded systems contain many features which may have security vulnerabilities and present problems to implement security solutions. Such features include, but are not limited to, non-standard operating systems, a variety of system services and management interfaces, debugging facilities, monitoring interfaces, access to and control over device resources, and wide area networks (WAN). In many embedded systems, operations may be performed on the system through the use of different interfaces and features. As an example, an embedded system may
